Heart Disease UCI - Unsupervised Learning

February 21, 2022

1 IBM Unsupervised Learning Capstone Project

by Marwan Khalil

1.1 Introduction

The heart is an amazing organ. It continuously pumps oxygen and nutrient-rich blood throughout your body to sustain life. This fist-sized powerhouse beats (expands and contracts) 100,000 times per day pumping 23,000 liters (5,000 gallons) of blood every day. To work properly, the heart (just like any other muscle) needs a good blood supply.

A heart attack (also known as myocardial infarction; MI) is defined as the sudden blockage of blood flow to a portion of the heart. Some of the heart muscle begins to die during a heart attack, and without early medical treatment, the loss of the muscle could be permanent.

Conditions such as high blood pressure, high blood cholesterol, obesity, and diabetes can raise the risk of a heart attack. Behaviors such as an unhealthy diet, low levels of physical activity, smoking, and excessive alcohol consumption can contribute to the conditions that can cause heart attacks. Some factors, such as age and family history of heart disease, cannot be modified but are associated with a higher risk of a heart attack.

1.2 Dataset

For the exploration of the risk a person has to develop a heart attack, the Heart Attack Analysis & Prediction Dataset from *kaggle.com* was utilized. It consists of:

- Age of the patient (age in years)
- Sex of the patient (sex; 1 = male, 0 = female)
- Exercise induced angina (exng; 1 = yes, 0 = no)
- Number of major vessels (ca; 0-3)
- Chest pain type (cp; Value 1: typical angina, Value 2: atypical angina, Value 3: non-anginal pain, Value 4: asymptomatic)
- Resting blood pressure (trestpbs; in mm/Hg on admission to the hospital)
- Cholesterol levels (chol; in mg/dl)
- Fasting blood sugar (fbs; if > 120 mg/dl, 1 = true; 0 = false)
- Resting electrocardiographic results (rest_ecg; 0 = normal, 1 = having ST-T wave abnormality, 2 = showing probable or definite left ventricular hypertrophy by Estes' criteria)
- Maximum heart rate achieved (thalach)
- Chance of heart attack (target: Heart disease)

- A blood disorder called thalassemia (thall; 1 = normal; 2 = fixed defect; 3 = reversable defect)
- Previous peak (oldpeak; ST depression induced by exercise relative to rest 'ST' relates to positions on the ECG plot)
- Slope (slp; the slope of the peak exercise ST segment, Value 1: upsloping, Value 2: flat, Value 3: downsloping)

1.2.1 Acknowledgements

```

1.2.2 Aim

The aim of this project is to apply unsupervised learning techniques to find whether an individual will develop a heart attack risk or not. More specifically, after some feature engineering and exploratory data analysis, the k-means and agglomerative clusteing algorithms will be explored.

1.3.2 K-Means Clustering

The scaled data was fitted to a k-means clustering model to determine the optimal number of clusters over a range of 1 to 13 clusters. The diagram below shows a plot of inertia versus clusters.

The plot of inertia versus number of clusters shows an elbow at number of clusters equal to 2, that is k = 2.

```
[27]: km = KMeans(n_clusters=2, random_state=42)
km = km.fit(heart_attack.drop('target', axis=1))

heart_attack['kmeans'] = km.predict(heart_attack.drop('target', axis=1))
(heart_attack[['target','kmeans']]
.groupby(['kmeans','target'])
.size()
.to_frame()
.rename(columns={0:'number'}))
```

```
[27]: number kmeans target 0 40 142 1 0 98 1 22
```

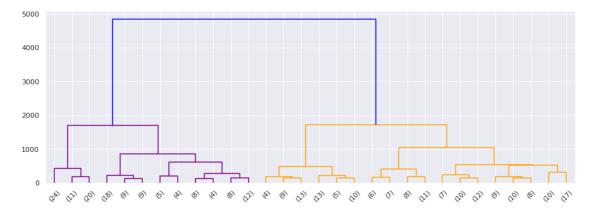

1.3.3 Agglomerative Clustering

```
[28]: for linkage in ['complete', 'ward']:
          ag = AgglomerativeClustering(n_clusters=2, linkage=linkage,__
       ag = ag.fit(heart_attack.drop('target', axis=1))
          heart_attack[str('agglom_'+linkage)] = ag.fit_predict(heart_attack.

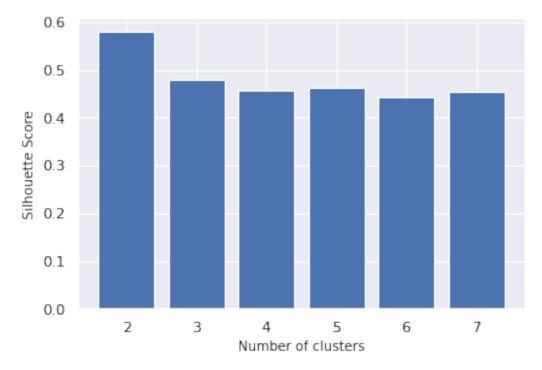

drop('target', axis=1))

```

The diagram below shows the dendrogram for the Hierarchical Agglomerative Clustering model.

```
# Plotting a bar graph to compare the results
k = [2, 3, 4, 5, 6,7]
plt.bar(k, silhouette_scores)
plt.xlabel('Number of clusters', fontsize = 10)
plt.ylabel('Silhouette Score', fontsize = 10)
plt.show()
```

1.4 Conclusion

1.4.1 Findings

From the abovementioned analysis, a few important findings can be outlined. Performing both K-means and agglomerative clustering algorithms, one could observe that the best model for the prediction of a potential myocardial infarction is the **Complete-link agglomerative technique**. On the contrary, for predicting those cases that there won't be any implications, the most suitable is the **Ward-link agglomerative clustering**. From both the dendrogram and the silhoute score plots, it is evident that the optimal number of the clusters is **two**.

1.4.2 Next steps

As a further suggestion, a DBSCAN could be implemented, following a Principal Component Analysis.
